Comment [MSF_EPAR61]: Correct to date of latest draft

MEMORANDUM

To: Ellen Belk, EPA Region 6
Cc: Katherine Heller, RTI International
From: Uarporn Nopmongcol, Greg Yarwood
Subject: 2018 Base Case CAMx Simulation, Texas Regional Haze Evaluation
[Contract EP-W-011-029]

ENVIRON is assisting EPA by performing modeling of regional haze impacts of selected sources in Texas.¹ The analysis builds upon modeling of 2002 and 2018 conducted previously for CENRAP by ENVIRON. The CENRAP database was enhanced to include a 12 km grid over Texas and nearby Class I areas, and updated to use with the latest version of the Comprehensive Air Quality Model with extensions (CAMx; ENVIRON, 2012). A memorandum presenting the 2002 baseline modeling results has been submitted to EPA (ENVIRON, 2013). This memorandum documents the new 2018 base case modeling setup, with changes to emissions at selected units by EPA ([detailed in the “Preparing Emissions Data” section below](#)), and results utilizing PSAT and PiG tools.

INTRODUCTION

The Clean Air Act (CAA) establishes special goals for visibility in many national parks, wilderness areas, and international parks. Through the 1977 amendments to the Clean Air Act, Congress set a national goal for visibility as “the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Class I Federal areas which impairment results from manmade air pollution” [CAA § 7491\(a\)\(1\), \(a\)\(4\). See also \(40 CFR 51.300\)](#). The goal of the Regional Haze Rule (RHR) is to achieve natural visibility conditions at 156 Federally mandated Class I areas by 2064. To achieve this goal, the RHR has set up milestone years of 2018, 2028, 2038, 2048, 2058, and 2064 to monitor progress toward natural visibility conditions. The 2000-2004 period has been used by states as a baseline from which to demonstrate progress toward natural visibility conditions in 2018.

EPA Region 6 is presently under a court-ordered Consent Decree deadline regarding action on the Texas Regional Haze State Implementation Plan (SIP). Regional haze (RH) is linked to fine particulate matter (PM_{2.5}), for which EPA has a new standard. Air quality modeling is an important tool for determining whether a source can be reasonably expected to contribute to

¹ [List of selected sources was provided by EPA based on EPA’s examination of 2009 annual emissions and distance to nearest Class I area \(Q/d analysis\)](#)

visibility impairment at a Class I area. ENVIRON is assisting EPA to evaluate regional haze impacts of sources in Texas that may be used to assess the Texas Regional Haze Implementation Plan.

The Texas RH analysis was built upon the regional photochemical modeling (ENVIRON and CERT, 2007) conducted for CENRAP. In particular, the CENRAP 2002 and 2018 36 km modeling database for CAMx was enhanced to include a 12 km grid over Texas and nearby Class I areas. The overall approach to the project includes the following steps:

- Update CENRAP 2002 and 2018 modeling database to use with the latest release of CAMx (v5.41) when the project began
- Conduct 2002 modeling with Plume-in-Grid (PiG) and a 12-km flexi-nested grid to provide the new 2002 baseline RH modeling
- Conduct 2018 modeling with PiG and the CAMx PM Source Apportionment Technology (PSAT) for sources selected by EPA
- Evaluate impact of individual sources selected by EPA on visibility in Class I areas
- Conduct any additional future-year scenarios to access various control strategies (to be determined)

This memorandum documents the new 2018 base case modeling setup and results.

CAMx MODELING APPROACH

Air quality modeling was performed with version 5.41 of the Comprehensive Air Quality Model with Extensions (CAMx; ENVIRON, 2012) with input data developed by CENRAP. The CAMx PM PSAT modeling was also conducted for the EPA selected sources' SO₂ and NO_x emissions (see Table 3 for a list of EPA selected sources). CAMx has changed since the CENRAP modeling and many CAMx inputs had to be updated. CAMx Input development and updates are described separately below.

2018 Annual 36 km CENRAP modeling database

The Texas RH analysis was built upon the 2018 annual regional photochemical modeling database developed as part of the CENRAP (ENVIRON and CERT, 2007). CENRAP developed a 2018 annual modeling database for CAMx on the 36 km unified national Regional Planning Organization (RPO) grid that covers the continental United States. The CENRAP modeling protocol (Morris et al., 2004), CENRAP modeling Quality Assurance Program Plan (QAPP; Morris and Tonnesen, 2004), and base model evaluation (ENVIRON and CERT, 2007) reports provide details on the development of the CENRAP 2002 and 2018 36 km annual modeling database. Emissions inputs for this study were based on the 2018 Base G (Base18G) which was projected from the 2002 Typical G (Typ02G) inventory. CENRAP went through numerous iterations of the emissions modeling before arriving at the final Base G emission inventories (e.g., Morris et al., 2005).

Enhancement to the CENRAP 2018 Modeling Database

Similar to the 2002 modeling setup, the CENRAP Base G 2018 36 km annual CAMx photochemical modeling database was updated to include a 12 km nested-grid that covers Texas and Class I areas in and near Texas including:

- National Parks: Big Bend (BIBE), Guadalupe Mountains (GUMO), and Carlsbad Caverns;
- Wildlife Refuges: Salt Creek (SACR) and Wichita Mountains (WIMO);
- Wilderness Areas: Breton (BRET), White Mountain (WHIT), Caney Creek (CACR), Upper Buffalo (UPBU), Bandeller (BAND), Hercules-Glade (HEGL), and others (see Table 1).

Figure 1 displays the 36/12 km nested grid for the CAMx modeling. The locations of Interagency Monitoring of Protected Visual Environments (IMPROVE) sites that includes Class I areas within and near the 12 km modeling domain are shown in Figure 2. The CAMx flexi-nesting feature was used to specify a 12 km Texas fine grid within the CENRAP 36 km modeling domain. Full flexi-nesting was invoked in which CAMx internally interpolates meteorological data, gridded emissions and other inputs from the 36 km grid to the 12 km grid. Flexi-nesting does not interpolate point source emissions because exact source coordinates are known enabling each point source to be placed within the correct 36 km or 12 km grid cell.

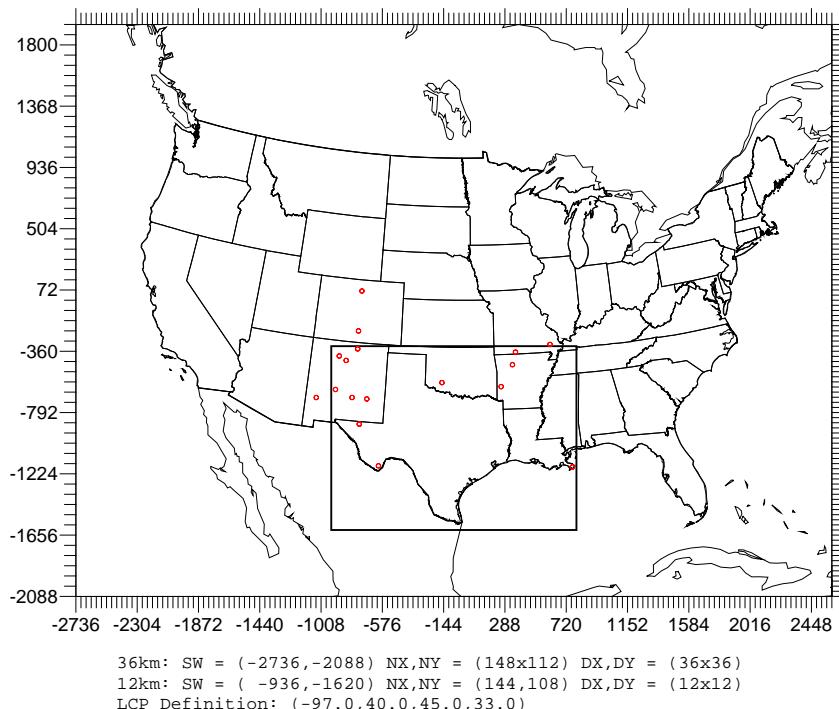

Figure 1. Texas RH modeling 36/12 km modeling domain and the locations of the IMPROVE monitoring sites that include Class I areas, indicated by circles.

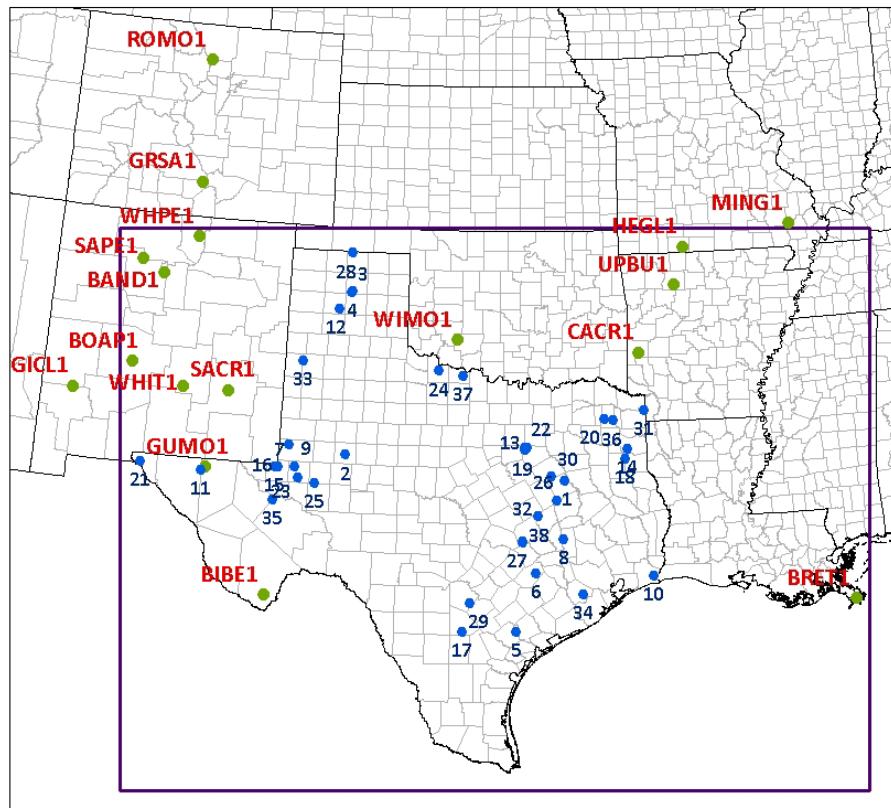

Figure 2. Texas RH modeling 12 km modeling domain, the locations of the IMPROVE monitoring sites (circles) and selected sources (indicated by Source ID numbers).

Table 1. Class I areas included in the Texas RH analysis.

Preparing Emissions Data

The 2018 emissions were processed consistently with the 2002 emissions. This study used the latest SMOKE version 3.1, although some SMOKE modules came from an older version to maintain compatibility with the format of data from CENRAP. All SMOKE configurations and SMOKE input files were the same as used in CENRAP with selected updates. Provided below is a summary of the emission updates made for this study.

- Updated emissions to 8 facilities and added one new facility:
 - One new unit at Sommers/Deely/Spruce power plant site
 - Two new units at Sandow 5 Generating Plant (new plant)
 - Three new units at WA Parish Station carried over from the 2002 CENRAP inventory and emission changes to one existing unit
 - Emission changes at North Texas Cement (Ash grove) to reflect shutting down two units and rebuilding the third unit

- Emission changes to reflect recently installed controls or improvements in control efficiencies on power plants at Sommers/Deely/Spruce, Big Brown, Gibbons Creek, Sandown Steam Electric Station, Monticello Steam Electric Station, and Fayette Power Project
- Used CB05 chemical speciation profiles for area and point sources
- Processed point source emissions in CAMx input format to preserve stack parameters and location
- Changed the earth sphere variable (IOAPI_ISPH) in SMOKE from 19 to 20. CENRAP SMOKE setup used IOAPI_ISPH=19 that could cause inconsistencies between point source locations and the meteorological points. IOAPI_ISPH=20 assumes a 6740 km earth radius consistent with MM5 and CAMx
- Selected Plume-in-Grid (PiG) for large SO₂ and NOx sources
- Assigned PSAT tagging group for each EPA selected source
- Added organic aerosol precursor emissions for biogenic sources based on CENRAP BEIS CB4 emissions
- Adjusted primary organic aerosol mass from POC to POA as required by CAMx

The criteria used to specify point sources as elevated and select elevated source for PiG treatment are described below:

Non-Selected sources

- A plume rise cutoff of 50 meter (i.e., any source having estimated plume rise lower than 50 m. was treated as a surface source).
- NOx emissions thresholds for PiG selection varied by region: 5 tons per day (TPD) for Texas, 10 TPD for neighboring states (NM, CO, OK, AR, LA, and KS), and 20 TPD for the rest.

Selected sources

- All selected sources were treated as elevated sources
- PiG criteria are stack height of 50 ft and NOx or SO₂ emissions higher than 20 TPD

Emissions Summary

A summary of emission updates at the unit level is shown in Table 2. Stack parameters of major units for the 38 selected sources are listed in Appendix A. Quality assurance of the SMOKE emissions processing conducted for the project included the development of emission summaries based on the raw inventory data input to the SMOKE processing system (IDA files) and daily emission reports from SMOKE. Table 3 summarizes the emission inventory data input to SMOKE from the IDA files (i.e., averages between the 'winter' and 'summer' files) for the 38 selected sources. Table 4 presents the emissions data after SMOKE processing. Note differences between the input and output are related to the temporal and spatial allocation within SMOKE, as well as numerical rounding of the data. Specifically, the discrepancies of emissions at two facilities (about 7%), Tolk Station (FIPS 48279; Plant ID 18) and Harrington Station (FIPS 48375; Plant ID 22), are due to temporal processing. Both plants have monthly temporal profiles which are stack-specific. However, from October-December, the CENRAP temporal cross-reference (stack-specific) points to more generic profiles rather than stack-

specific profiles. We note that the 2018 emission inventory includes an estimate of emission reductions due to Clean Air Interstate Rule (CAIR) at Texas electricity generating units (EGUs) and states in the eastern U.S. covered by CAIR. CAIR achieves reductions of NOx and SO₂ from power plants across 27 eastern states through state emission budgets and a cap and trade system to address contributions to ozone and PM in downwind states.

Table 2. Updates to annual emissions (TPY) of EPA selected sources by pollutant in the CENRAP 2018 Base G inventory.

Other CAMx Inputs

All other CAMx inputs including meteorological data, land-use files, albedo-haze-ozone inputs, photolysis rates, boundary and initial conditions were the same as used in the 2002 baseline modeling.

CAMx Model Configuration

The CAMx configuration was the same as used in the 2002 baseline modeling except that the PSAT source tagging feature was turned on (Table 5). The CAMx model was run separately for each of four quarters of 2018 using a 15 day spin up period to limit the influence of the assumed initial concentrations.

Table 5. Model configurations options for CAMx model.

Science Options	Texas RH
Version	Version 5.41
Vertical Grid Mesh	19 Layers
Horizontal Grids	36/12 km using two-way nesting
Initial Conditions	15 days full spin-up
Boundary Conditions	2002 GEOS-CHEM day specific 3-hour average data
Sub-grid-scale Plumes	PiG treatment
Chemistry	
Gas Phase Chemistry	CB05
Aerosol Chemistry	ISORROPIA equilibrium
Secondary Organic Aerosols	SOAP
Cloud Chemistry	RADM-type aqueous chemistry
Meteorological Processor	MM5CAMx v5.2
Horizontal Transport	
Eddy Diffusivity Scheme	K-theory with Kh grid size dependence
Source Apportionment	PSAT (sulfur, nitrogen, and primary PM)
Vertical Transport	
Eddy Diffusivity Scheme	K-Theory
Diffusivity Lower Limit	Kzmin = 0.1 to 1.0 (Land use dependent Kzmin)
Planetary Boundary Layer	From MM5 with PBL below convective clouds raised to cloud top
Deposition Scheme	Zhang
Numerics	
Gas Phase Chemistry Solver	Euler Backward Iterative (EBI) solver
Horizontal Advection Scheme	Piecewise Parabolic Method (PPM scheme)
Parallelization	OMP-MPI

PSAT Formulation

PSAT is designed to source apportion the following PM species modeled in CAMx:

- Sulfate (SO_4)
- Particulate nitrate (NO_3)
- Ammonium (NH_4)
- Particulate mercury ($\text{Hg}(\text{p})$)
- Secondary organic aerosol (SOA)
- Six categories of primary particulate matter (PM)
 - Elemental carbon (EC)
 - Primary organic aerosol (POA)
 - Fine crustal PM (FCRS)
 - Fine other primary PM (FPRM)
 - Coarse crustal PM (CCRS)
 - Coarse other primary PM (CPRM)

PSAT performs PM source apportionment (also called source tagging) for each selected source group. A source group may consist of a combination of geographic regions and emissions source categories. For this study, each EPA selected facility is assigned a unique PSAT source group. The PSAT “reactive tracers” that are added for each source group (i) are described below. In general, a single tracer can track primary PM species, whereas secondary PM species require several tracers to track the relationship between gaseous precursors and the resulting PM. Particulate nitrate and secondary organics are the most complex species to apportion because the emitted precursor gases (NO_x and VOCs) are several steps removed from the resulting PM species (NO_3 and SOA). There is a PSAT convention that tracer names for particulate species begin with the letter “P.” This study tracks sulfur, nitrogen and primary particulate matter tracers:

Sulfur (SO_4 Tracers)

SO2_i Primary SO_2 emissions

PS4_i Particulate sulfate ion from primary emissions plus secondarily formed sulfate

Nitrogen (NO_3 Tracers)

RGN_i Reactive gaseous nitrogen including primary NO_x ($\text{NO} + \text{NO}_2$) emissions plus nitrate radical (NO_3), nitrous acid (HONO) and dinitrogen pentoxide (N_2O_5).

TPN_i Gaseous peroxy acetyl nitrate (PAN) plus peroxy nitric acid (PNA)

NTR_i Organic nitrates (RNO_3)

HN3_i Gaseous nitric acid (HNO_3)

PN3_i Particulate nitrate ion from primary emissions plus secondarily formed nitrate

NH3_i Gaseous ammonia (NH_3)

PN4_i Particulate ammonium (NH_4)

Primary Particulate Matter (PM Tracers)

PEC_i Primary Elemental Carbon

POA_i Primary Organic Aerosol

PFC_i Fine Crustal PM

PFN_i Other Fine Particulate

PCC_i Coarse Crustal PM

PCS_i Other Coarse Particulate

One fundamental assumption in PSAT is that PM is apportioned back to the primary precursor for each type of PM. For example, SO₄ is apportioned to SO_x emissions, NO₃ is apportioned to NO_x emissions, NH₄ is apportioned to NH₃ emissions, etc.

CAMx MODELING RESULTS

Air quality modeling results for the 2018 base case simulation are presented by pollutant of concern, including ozone and PM. The analysis of air quality results focuses on high ozone and PM levels, i.e. maximum 8-hour ozone and maximum 24-hour PM. Annual average levels for PM and its constituents are also presented. This section also provides analysis of visibility contribution at Class I areas due to selected sources. Comparison of a reasonable progress goal to a glide [slope-path](#) for each Class I area is provided at the end of this section.

Ozone

The annual maximum 8-hour ozone may be susceptible to emissions/model artifacts so we focus on the annual 4th highest 8-hour ozone (Figure 3). Similar to the 2002 results, the 2018 base case shows high values of 4th highest daily maximum 8-hour ozone (above 75 ppb, the current level of the ozone NAAQS) in several western locations associated with wildfire emissions and over water bodies close to major urban/industrial areas near the Great Lakes, Gulf Coast and the Northeast Seaboard, where emissions are transported over water and confined to a shallow boundary layer. The 2018 ozone is lower than the 2002 ozone in most eastern states. Nonetheless, ozone exceeds 75 ppb in several urban areas in Texas including Dallas and Houston. New Orleans and Baton Rouge, Louisiana, also exceed over 75 ppb.

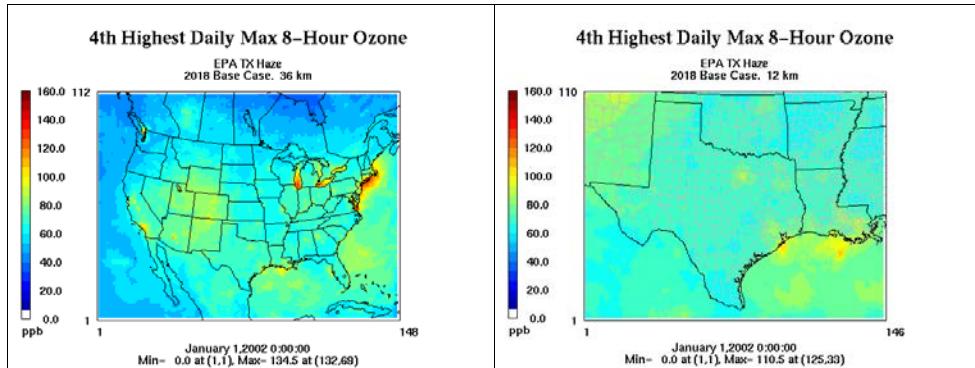

Figure 3. 4th highest daily maximum 8-Hour ozone (ppb) from the 36-km simulation (left) and 12-km simulation (right) for the 2018 base case.

Particulate Matter

PM_{2.5} results are presented for daily design-value relevant measures (98th percentile of all daily concentrations) and annual average concentrations. Overall, the 2002 and 2018 results have similar spatial patterns but the 2018 PM_{2.5} concentrations are lower. The 8th highest 24-hour average concentrations of PM_{2.5} (Figure 4) shows the highest peak values occurring in the Western United States but more uniformly high values occurring in the Eastern United States. Elevated PM_{2.5} concentrations in the 12 km domain are seen in western Louisiana and western Arkansas due to fire activities (also observed in the 2002 simulation). Similar PM compositions to the 2002 simulation are seen in the 2018 simulation (show in Appendix B). Specifically, high particulate matter concentrations in the Eastern United States have large sulfate and nitrate contributions with additional contributions from primary organic PM in the south. Urban PM_{2.5} in Texas (characterized by high nitrate and organic carbon) is lower in the 2018 simulation. Annual average concentrations of PM_{2.5} and PM₁₀ (Figure 5 and Figure 6) show a similar pattern of widespread but the fire influence is less pronounced.

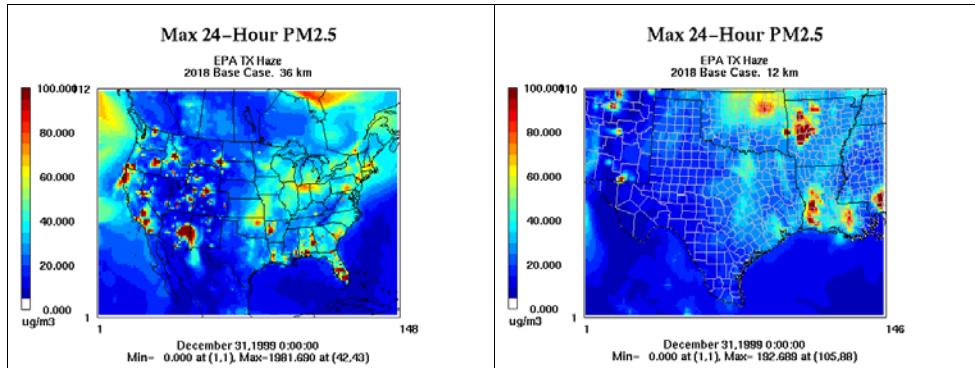

Figure 4. Maximum 24-Hour PM_{2.5} ($\mu\text{g m}^{-3}$) from the 36-km simulation (left) and 12-km simulation (right) for the 2018 base case.

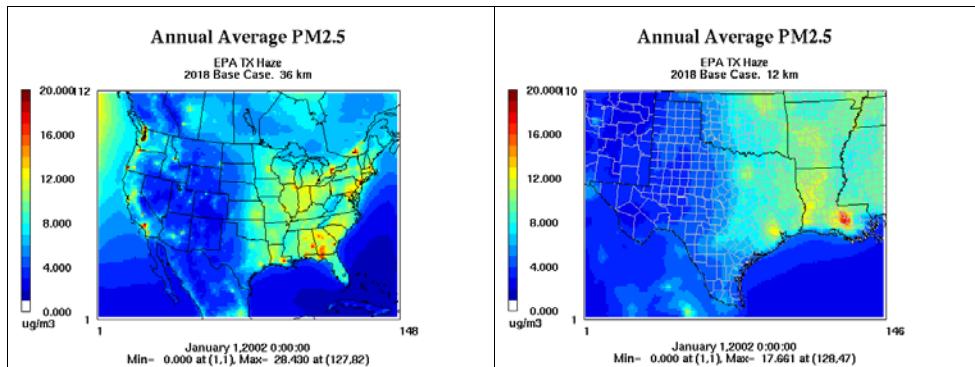

Figure 5. Annual average PM_{2.5} ($\mu\text{g m}^{-3}$) from the 36-km simulation (left) and 12-km simulation (right) for the 2018 base case.

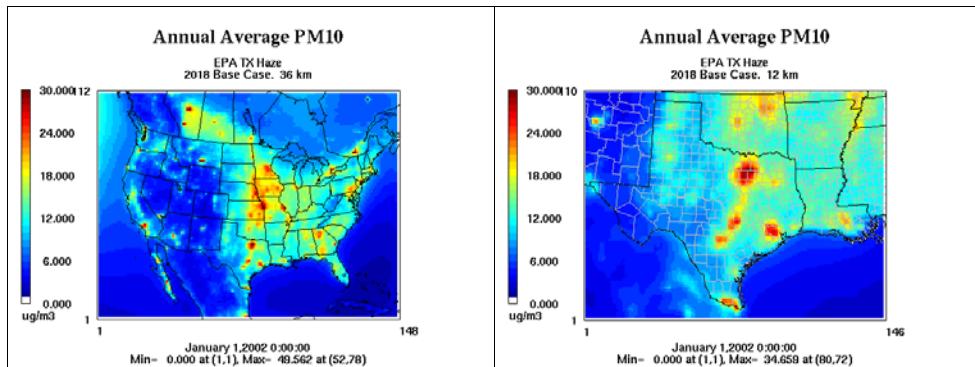

Figure 6. Annual average PM₁₀ ($\mu\text{g m}^{-3}$) from the 36-km simulation (left) and 12-km simulation (right) for the 2018 base case.

Visibility Contributions

Visibility impacts were calculated at each Class I area using 2018 PM concentrations from each PSAT group. Steps in conducting visibility contribution calculations are summarized below:

- Step 1. Use Modeled Attainment Test Software (MATS) to compute model-estimated relative response factors (RRFs) that are the ratio of the model-estimated 24-hour PM_{2.5} concentrations for the future-year (2018) to the baseline (2002) emission scenarios.
- Step 2. Calculate 2018 modeled visibility conditions and projected visibility conditions (using RRF approach) for 20% worst (W20%) and 20% best (B20%) days
- Step 3. To get individual source or group of sources contributions, subtract the PSAT results from the 2018 CAMx output for the source of interest, rerun MATS, and calculate differences of projected visibility conditions by repeating Step 2.

These procedures use the new IMPROVE algorithm (Pitchford et al., 2007) which reconstructs the light-extinction coefficient (bext, expressed in units of inverse megameters, Mm⁻¹) using the following equation:

$$\begin{aligned} \text{bext} \approx & 2.2 \times f_S(\text{RH}) \times [\text{small sulfate}] + 4.8 \times f_L(\text{RH}) \times [\text{large sulfate}] \\ & + 2.4 \times f_S(\text{RH}) \times [\text{small nitrate}] + 5.1 \times f_L(\text{RH}) \times [\text{large nitrate}] \\ & + 2.8 \times [\text{small organic mass}] + 6.1 \times [\text{large organic mass}] \\ & + 10 \times [\text{elemental carbon}] \\ & + 1 \times [\text{fine soil}] \\ & + 1.7 \times f_{SS}(\text{RH}) \times [\text{sea salt}] \\ & + 0.6 \times [\text{coarse mass}] \\ & + \text{Rayleigh scattering (site-specific)} \\ & + 0.33 \times [\text{NO}_2 (\text{ppb})] \end{aligned}$$

The apportionment of the total concentration of sulfate compounds into the concentrations of small and large size fractions is accomplished using the following equations:

$$\begin{aligned} [\text{large sulfate}] &= [\text{total sulfate}/20] \times [\text{total sulfate}], \text{ for } [\text{total sulfate}] < 20 \mu\text{g/m}^3 \\ [\text{large sulfate}] &= [\text{total sulfate}], \text{ for } [\text{total sulfate}] \geq 20 \mu\text{g/m}^3 \\ [\text{small sulfate}] &= [\text{total sulfate}] - [\text{large sulfate}] \end{aligned}$$

Similar equations are used to apportion total nitrate and total organic mass into small and large size fractions. The new algorithm contains three distinct water growth terms, designated f_S , f_L , and f_{SS} for the small and large sulfate and nitrate fractions, and for sea salt, respectively.

Monthly average $f(\text{RH})$ values are used as following FLAG2010 procedure (FLAG, 2010).

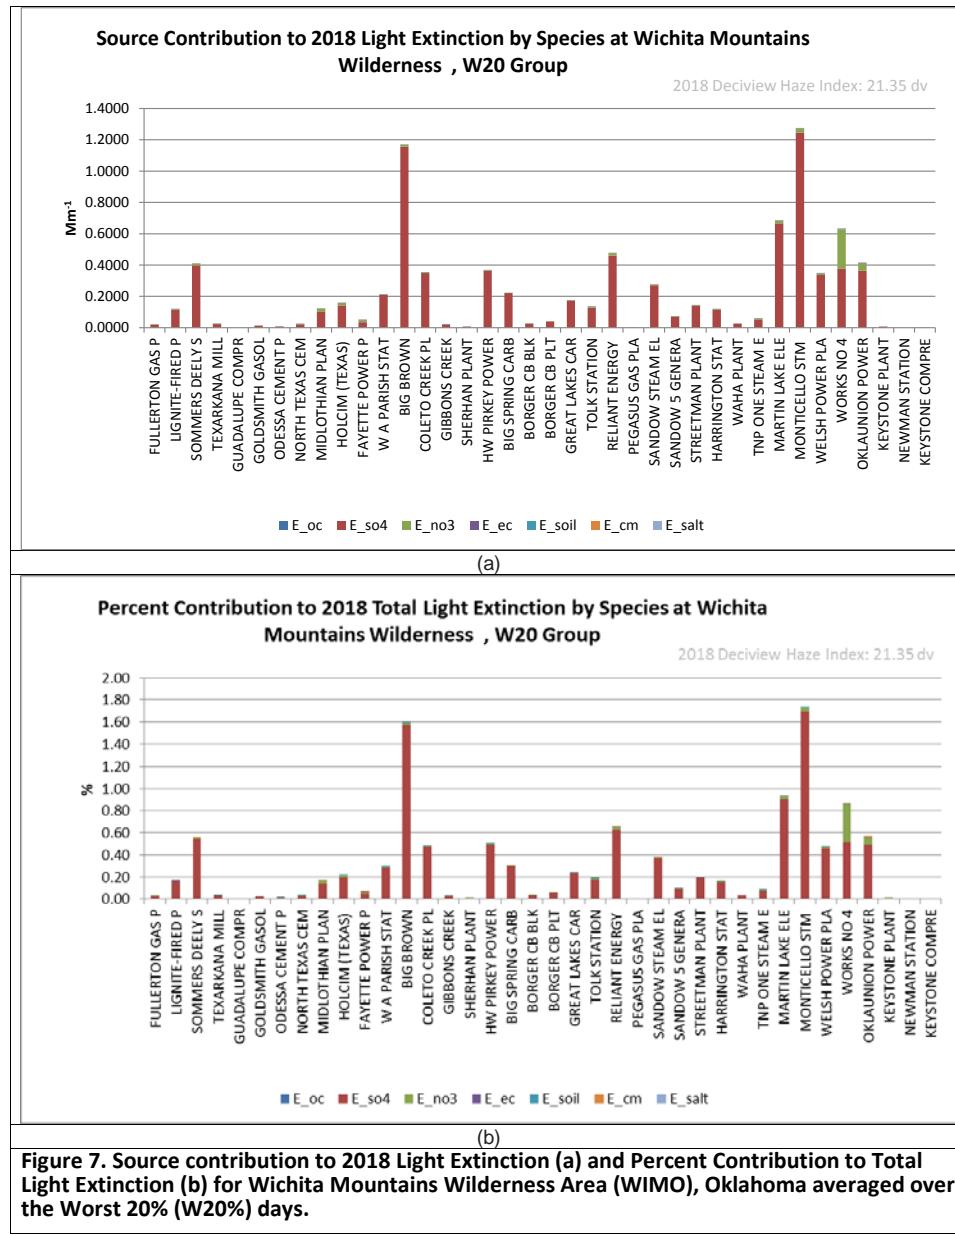

Our analysis calculates the day-specific visibility impacts at Class I areas on the B20% and W20% days. Figures 7-14 demonstrate visibility contributions at the Class I areas in Texas (i.e., Big Bend and Guadalupe Mountains) and near Texas (i.e., Caney Creek and Wichita Mountains)

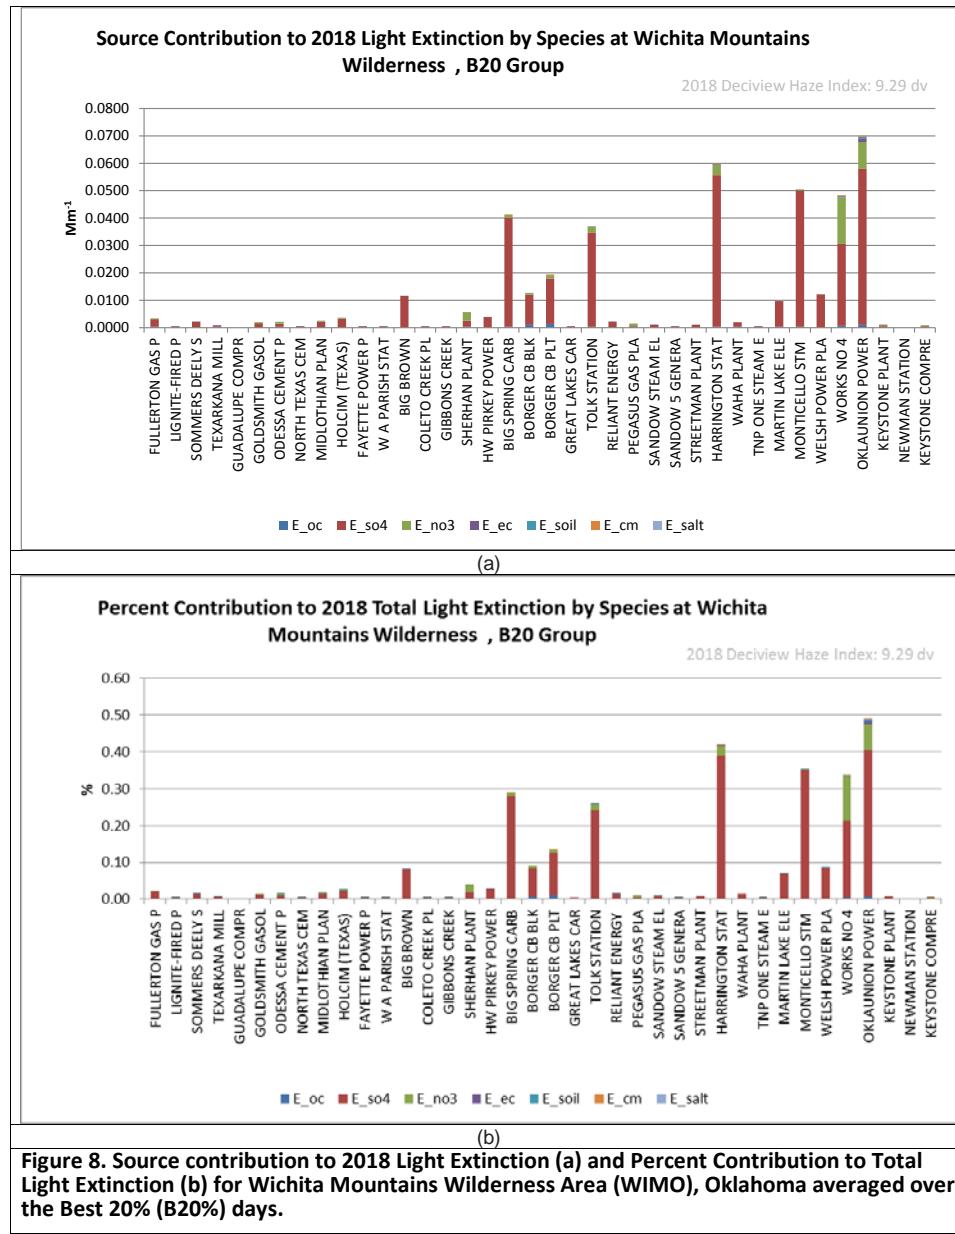

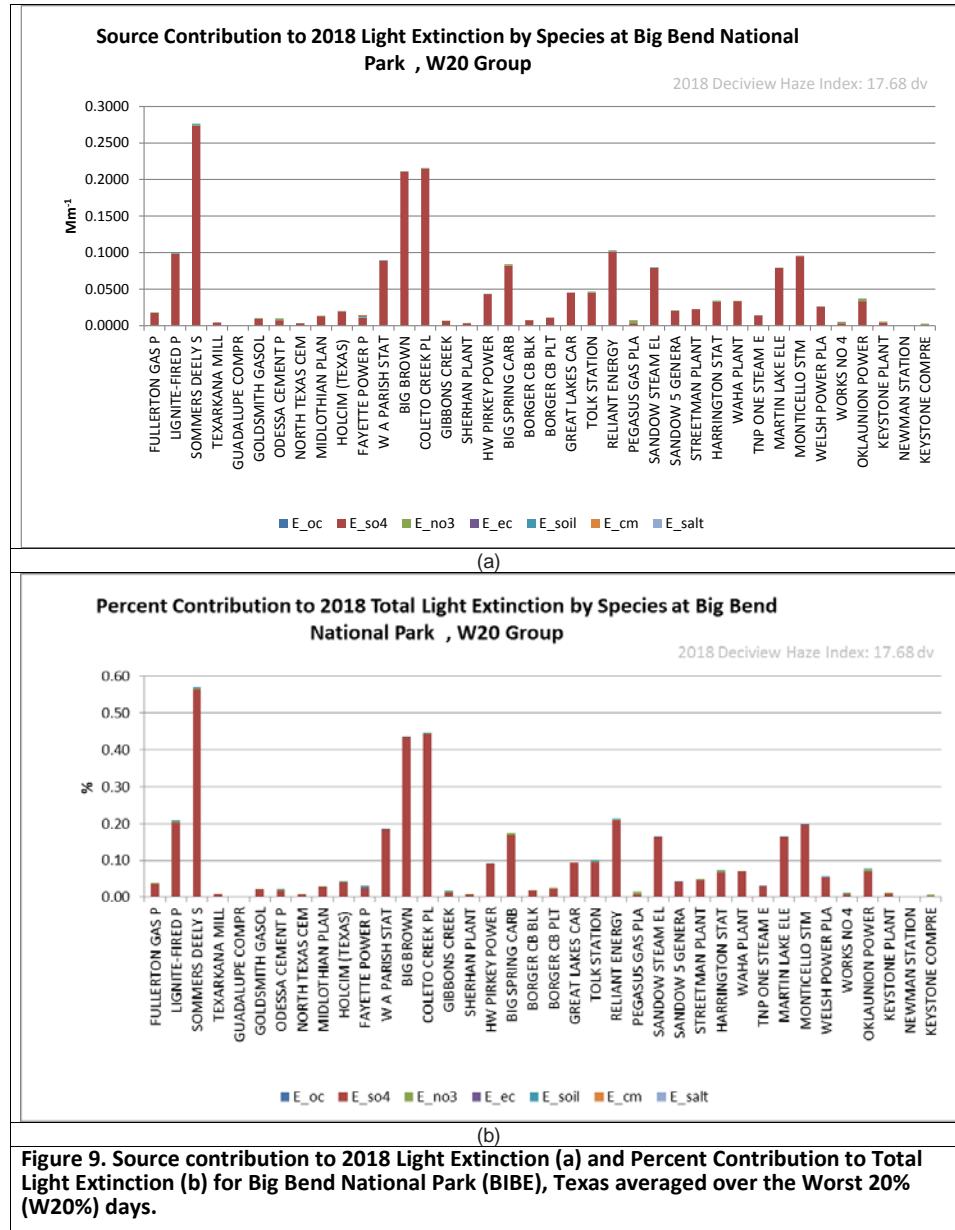

averaged over the B20% and W20% days. Additional types of graphics showing visibility contributions can be found in Appendix C and in supporting Excel Spreadsheets accompanying this memorandum.

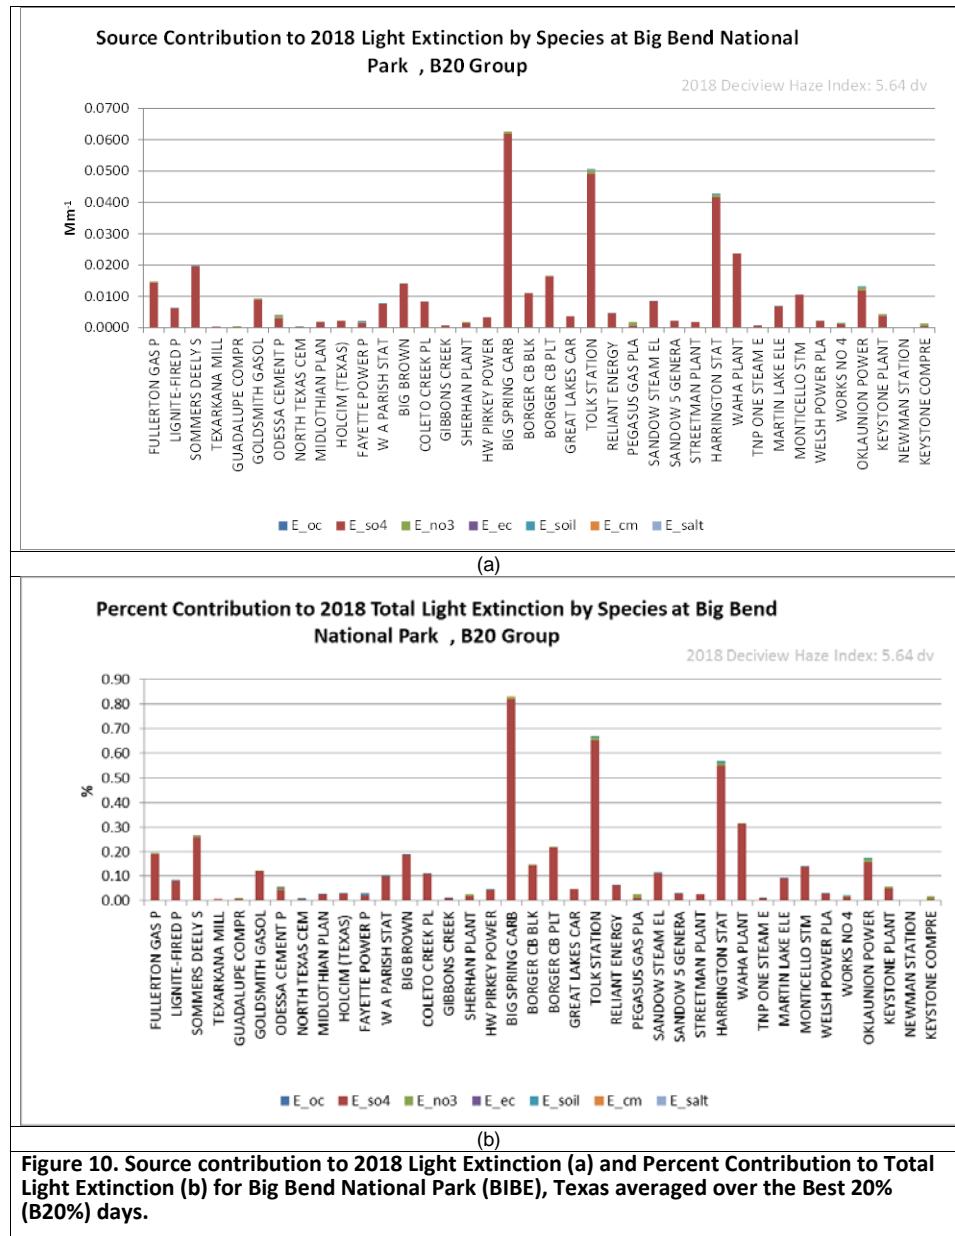

Sulfate appears to be the main constituent that contributes to visibility degradation at the Class I areas in/near Texas on both B20% and W20% cases. Although the 2002 visibility model performance shows underestimation of sulfate across all sites on the W20% days, the RRF approach makes use of model results in a relative sense to counter the model biases. The B20% days generally include more winter days than the W20% days, resulting in higher visibility contributions from nitrate. Proximity of the selected sources to Class I areas and magnitude of SO₂ emissions are factors that influence visibility impacts at these four Class I areas. A sensitivity test showed that projected visibility conditions and contributions are relatively unaffected by using an alternate RRF approach with RRF for coarse material and soil set to 1 (not shown here) on both 20% worst and 20% best days.

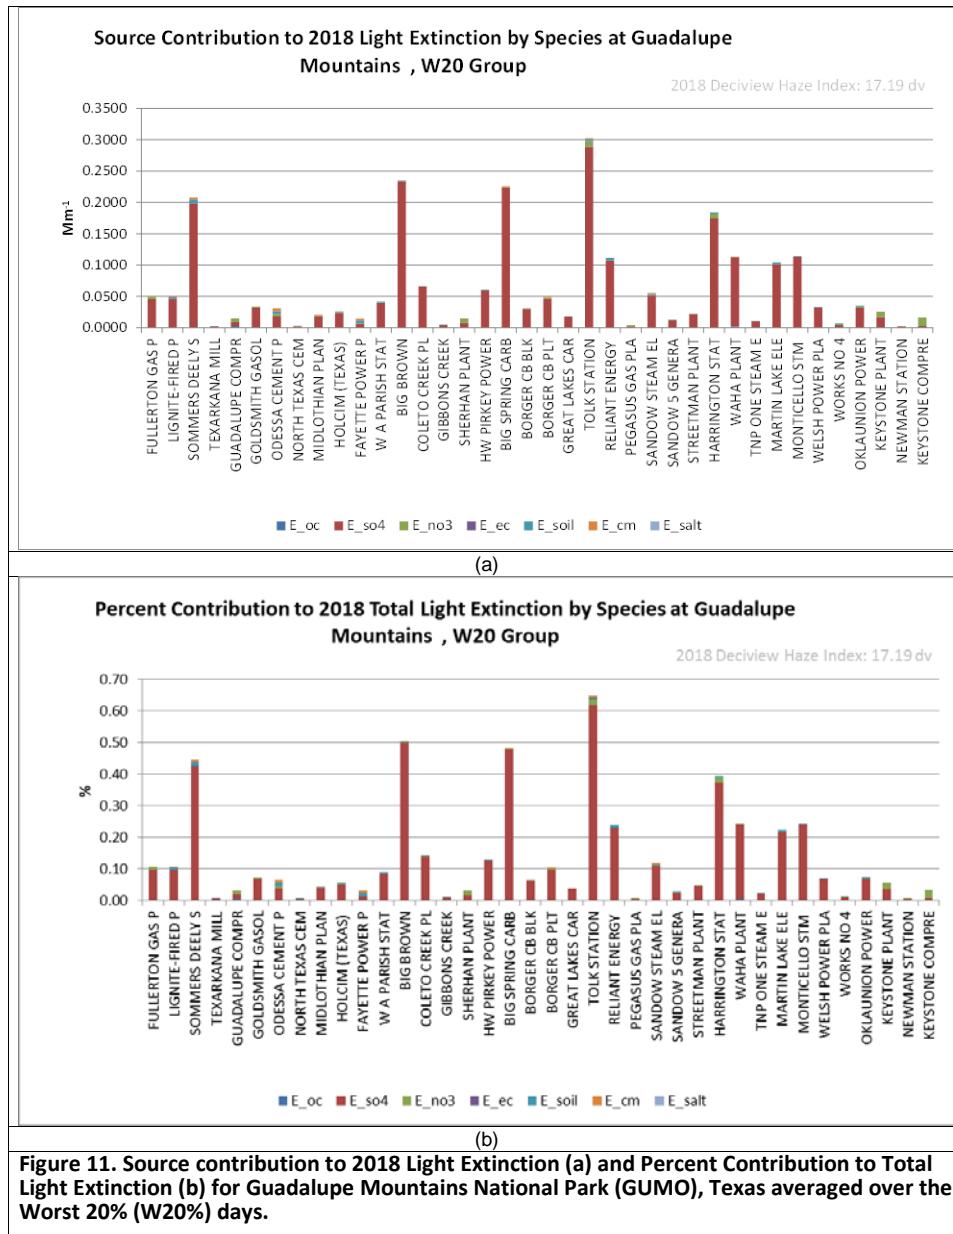

Top 10 facilities based on average and maximum visibility impacts on the worst 20% days at each Class I area are listed in Table 6.

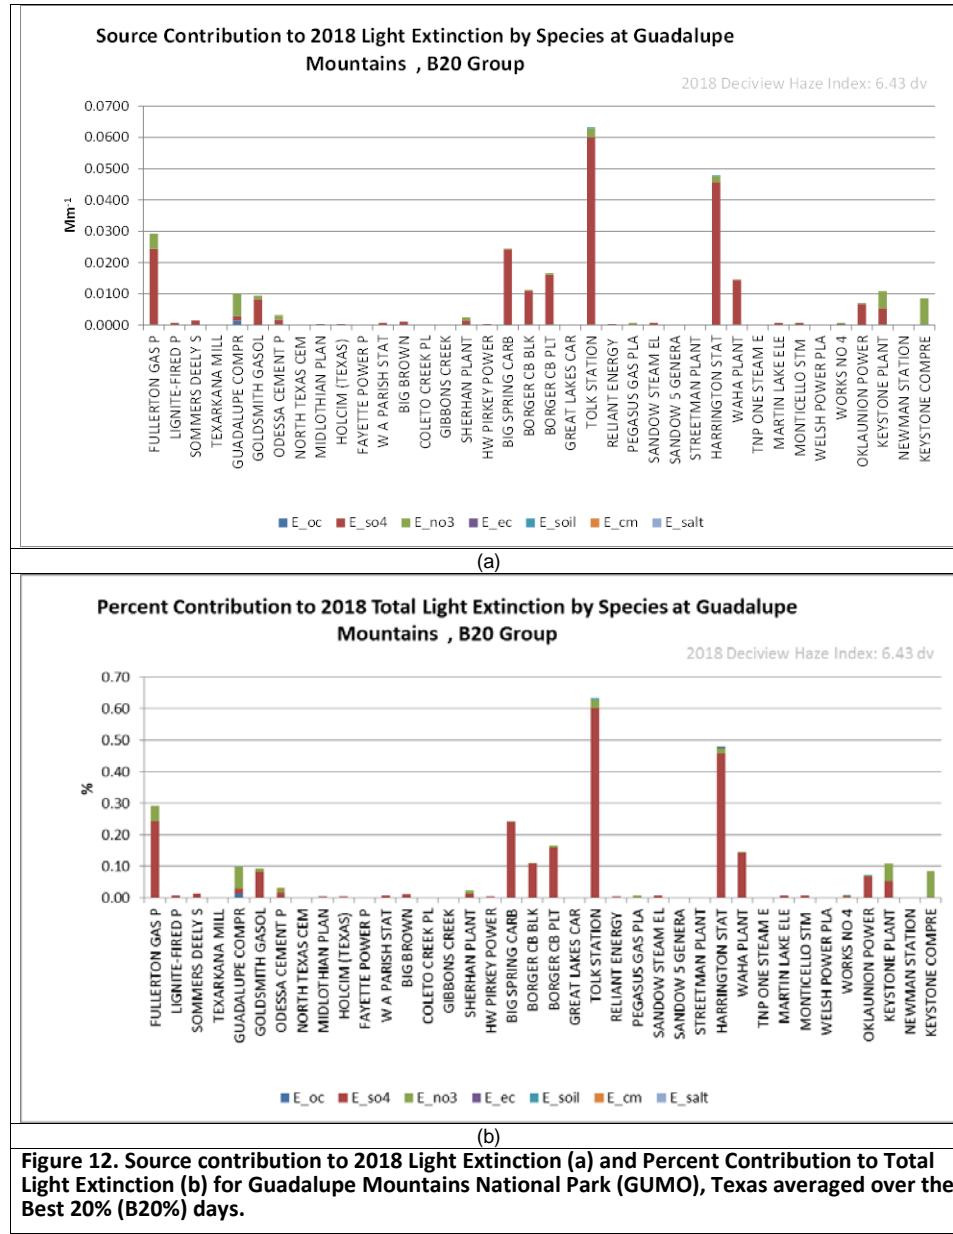

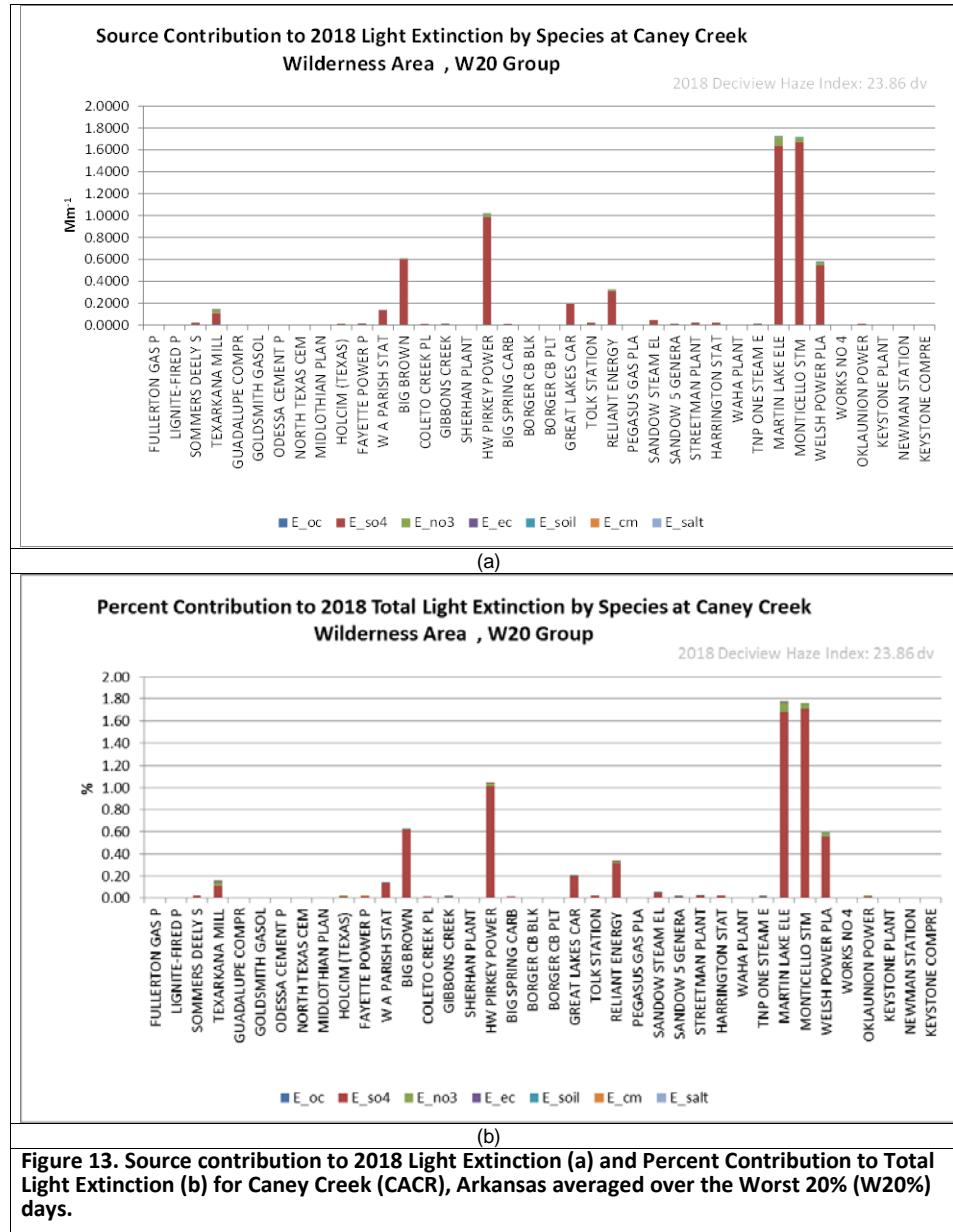

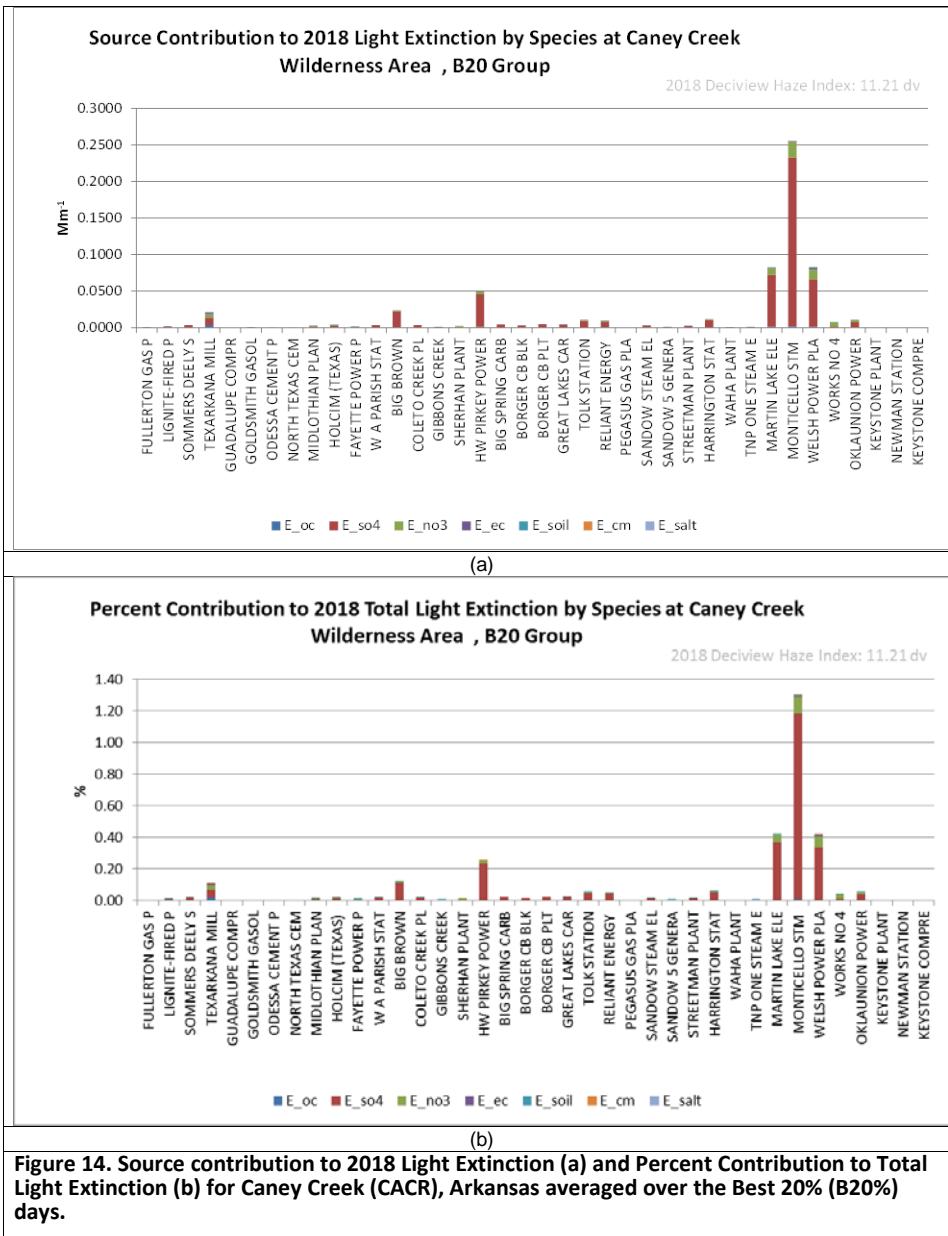

Table 6. Top 10 facilities based on average and maximum visibility impacts on the worst 20% days at each Class I area.

Uniform Rates of Progress and Projected 2018 Reasonable Progress Goals

In preparing a regional haze state implementation plan (SIP) each state must “analyze and determine the uniform rate of progress (glide path) needed to attain natural visibility conditions by the year 2064.” (40 Code of Federal Regulations (CFR) §51.308(d)(1)(i)(B)) Each state with one or more Class I areas must set a reasonable progress goal (measured in deciviews) for each of its Class I areas and compare the reasonable progress goal to the glide [slope-path](#) for the Class I area.

“The reasonable progress goals must provide for an improvement for the most impaired days [the worst 20 percent of monitored days] over the period of the implementation plan and ensure no degradation in visibility for the least impaired days [the best 20 percent of monitored days] over the same period.” (40 CFR §51.308(d)(1)) The period of the first regional haze SIP is from its adoption to 2018. The uniform rate of progress line is a straight line from the 2000 through 2004 base period impairment for the worst 20 percent of monitored days plotted from 2004 to natural conditions plotted for 2064.

The natural visibility conditions goal for the 20% worst days in 2064 in this study are the same as the natural conditions used in the CENRAP Technical Support Document (ENVIRON and CERT, 2007). The baseline values (2000-2004) are calculated by the MATS software using Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring site data. A glide path for the W20% days is a straight line from the baseline to 2064 natural condition at each Class I area; whereas a glide path for the B20% days is a straight horizontal line from the baseline value to the natural condition. Figures 15-18 show glide paths at four Class I areas. The green and red dots shown on each plot are 2018 projected visibility based on the CAMx model results. Additional graphics showing glidepaths can be found in Appendix C and in supporting Excel Spreadsheets accompanying this memorandum.

Similar analysis based on CMAQ simulation results was conducted by CENRAP for the worst and best 20% days and documented in Appendix D of the CENRAP Technical Support Document (ENVIRON and CERT, 2007). CENRAP analysis was provided here in Table 7 for comparison. In this study, the 2018 progress goals on the worst 20% days are not reached at all four Class I areas shown. However, the CENRAP modeling predicted that the 2018 goal is met at Caney Creek. No degradation in visibility occurs on the best 20% days. Overall, the projected visibilities appears to be comparable to the CENRAP projections on the worst and best 20% days (this study predicted slightly higher projected visibility)

SUMMARY

Air quality modeling results for the 2018 base case simulation are presented by pollutant of concern, including ozone and PM. Overall, the air quality maps show consistent spatial patterns between the 2002 and 2018 results with lower concentrations predicted in the 2018 base case. PM composition between the two simulations also is similar. The predicted 2018 ozone and PM concentrations are within reasonable ranges.

Sulfate appears to be the main constituent that contributes to visibility degradation at the Class I areas in/near Texas on both B20% and W20% cases. Proximity of the selected sources to Class I areas and magnitude of SO₂ emissions are factors that influence visibility impacts at nearby Class I areas. The Excel Spreadsheets accompanying this memorandum can be a useful tool in identifying sources that contribute to modeled visibility degradation.

The glide-path analysis shows that the 2018 progress goals on the worst 20% days are not reached at all four Class I areas shown in this report (i.e., WIMO, CACR, BIBE and GUMO). However, the CENRAP modeling predicted that the 2018 goal is met at Caney Creek. No degradation in visibility occurs on the best 20% days.
